

A Fusion Model of Seismic and Hydro-Acoustic Propagation for Treaty Monitoring

Nimar Arora, *Bayesian Logic*
Mark Prior, *CTBTO*

EGU2014-15796, 2014

Overview

- ◉ Probabilistic Generative Model
 - NET-VISA (NETwork processing Vertically Integrated Seismic Analysis)
 - NET-VISA + Hydro = NET-VISHA
- ◉ Learning Model Parameters
- ◉ Inference
- ◉ Results
- ◉ Results on Ahyl Seamount (active underwater Volcano)

The Model

Seismic
Event

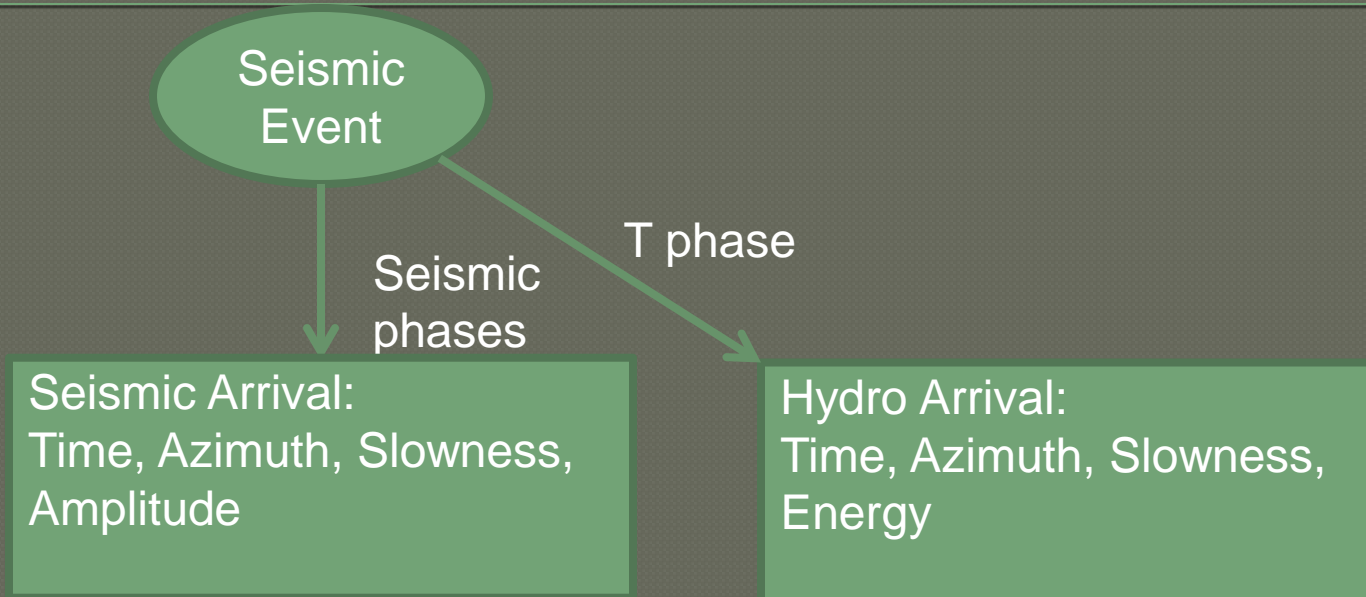

```
graph TD; A([Seismic Event]) -- Seismic phases --> B[Seismic Arrival: Time, Azimuth, Slowness, Amplitude];
```

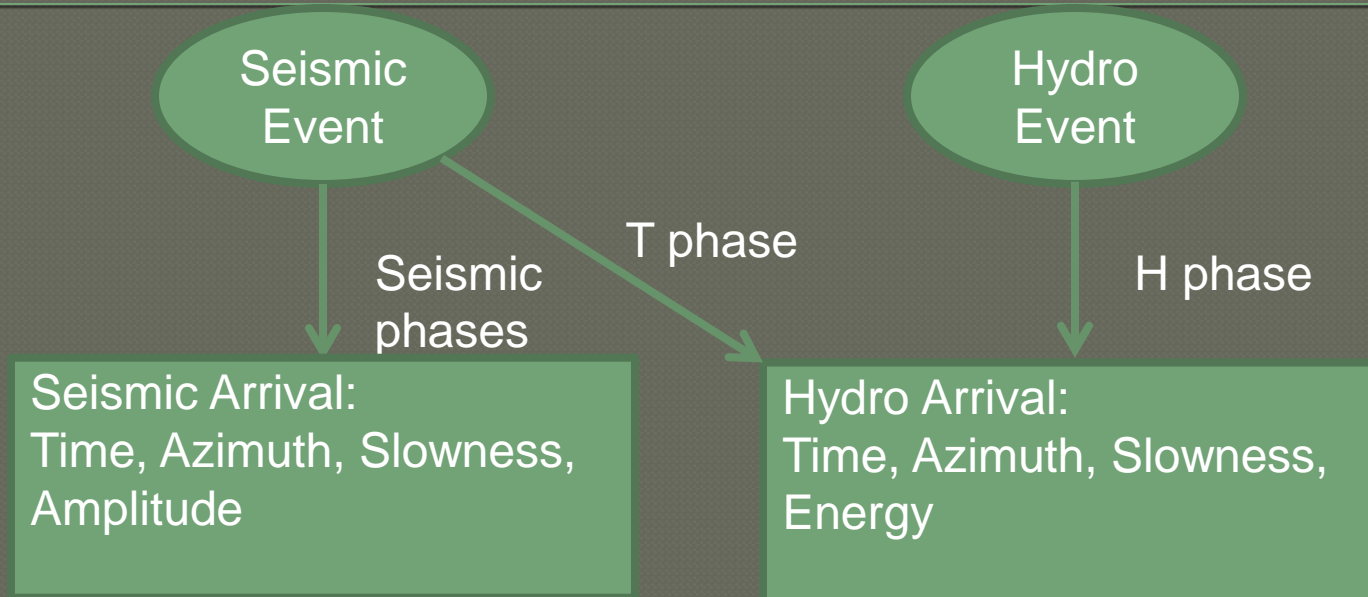

Seismic
phases

Seismic Arrival:
Time, Azimuth, Slowness,
Amplitude

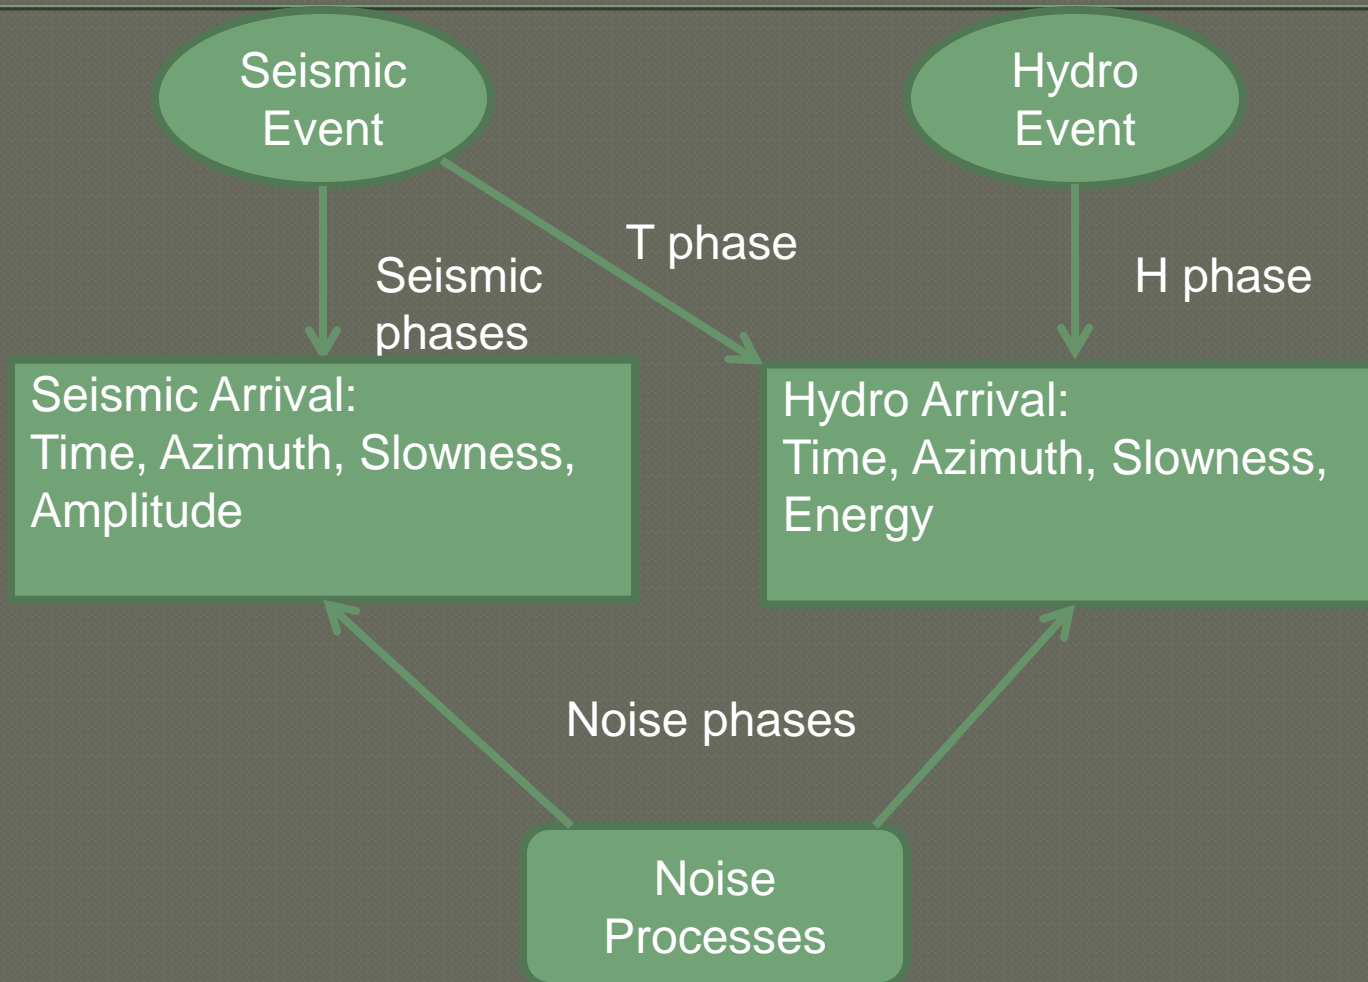

The Model

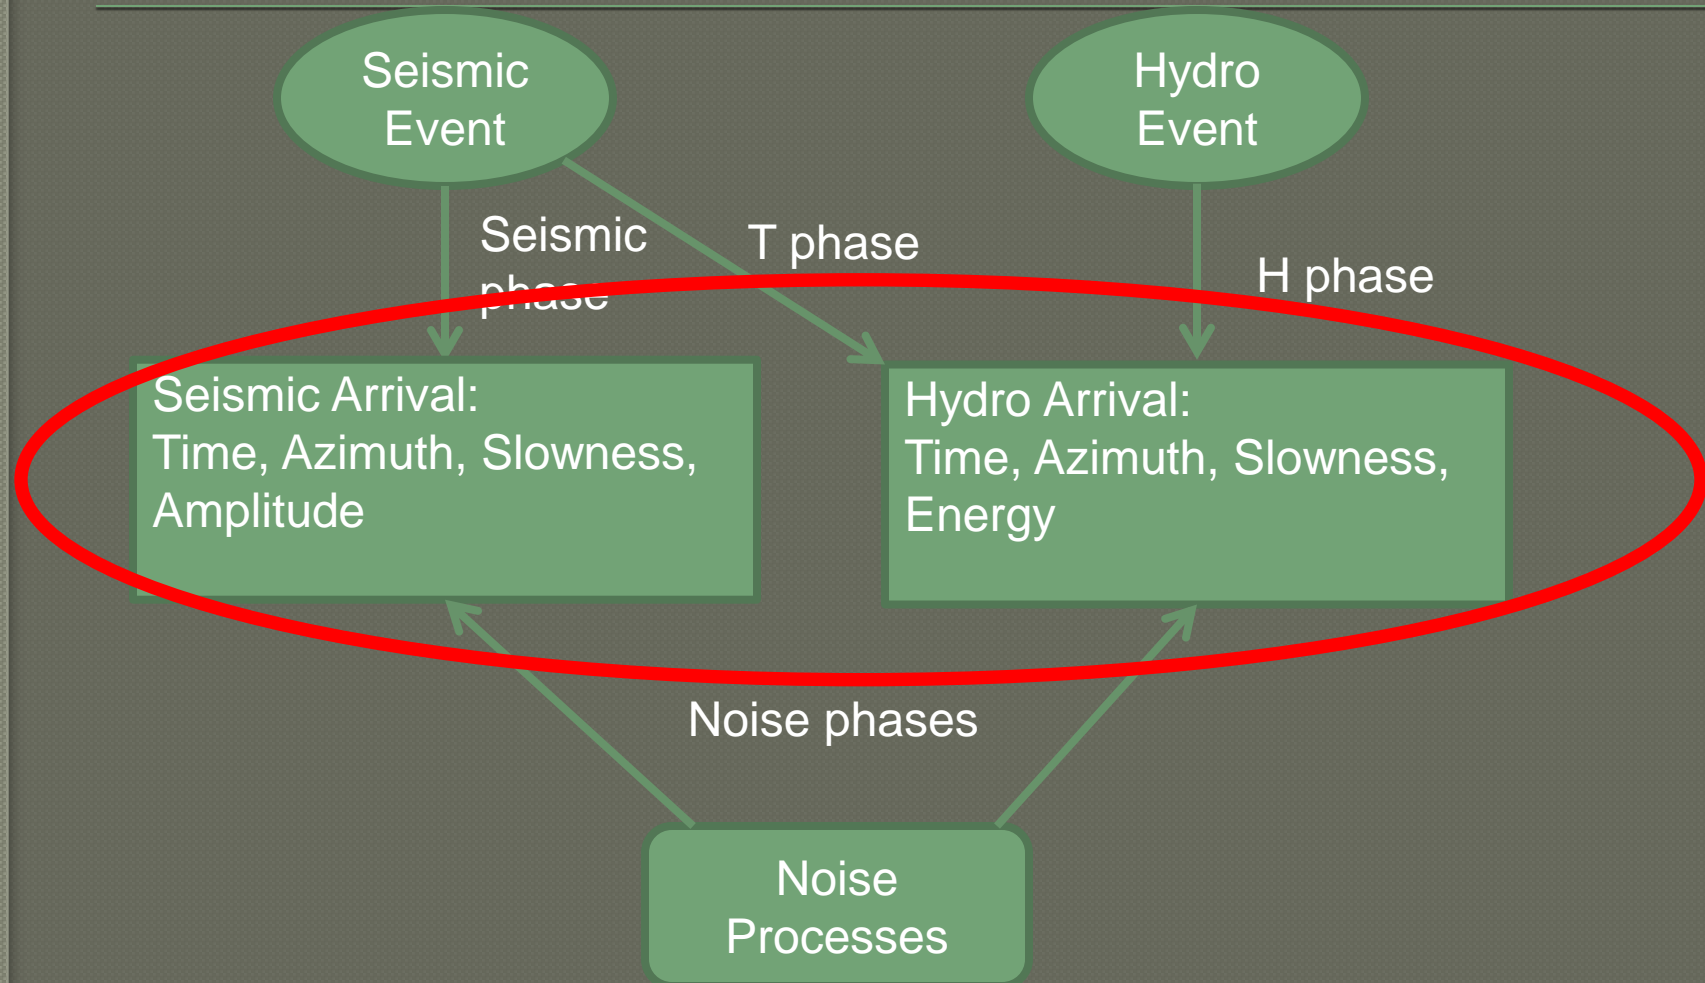

The Model

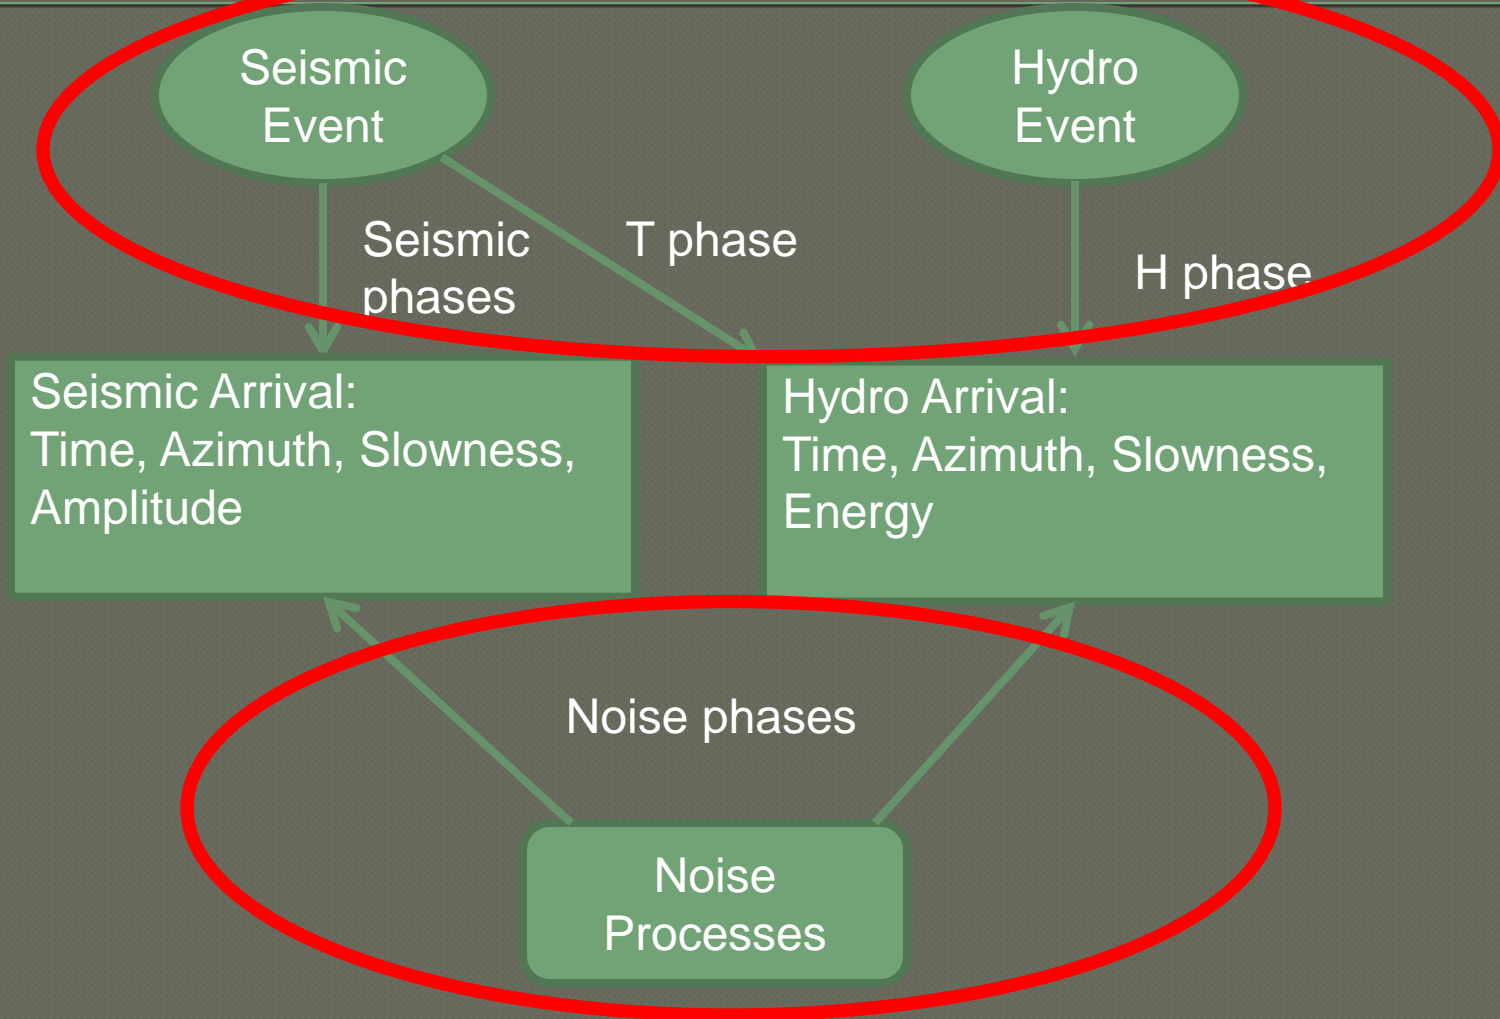

The Model

The Model

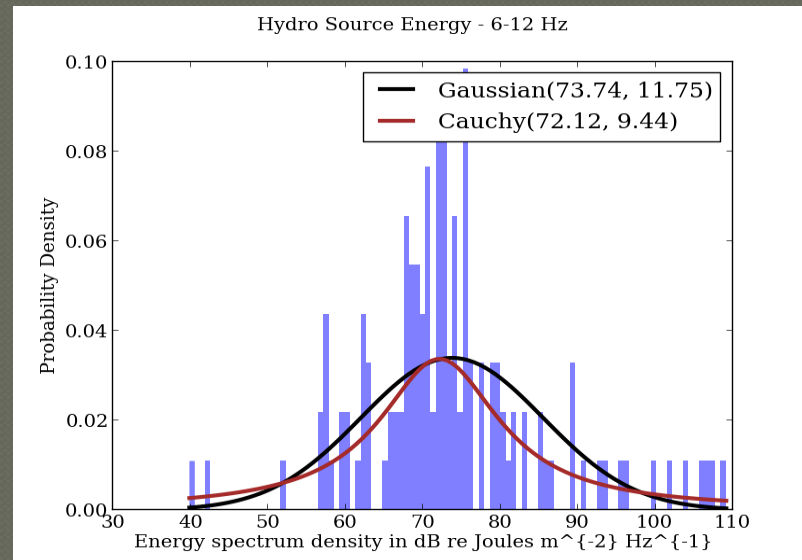

The Model

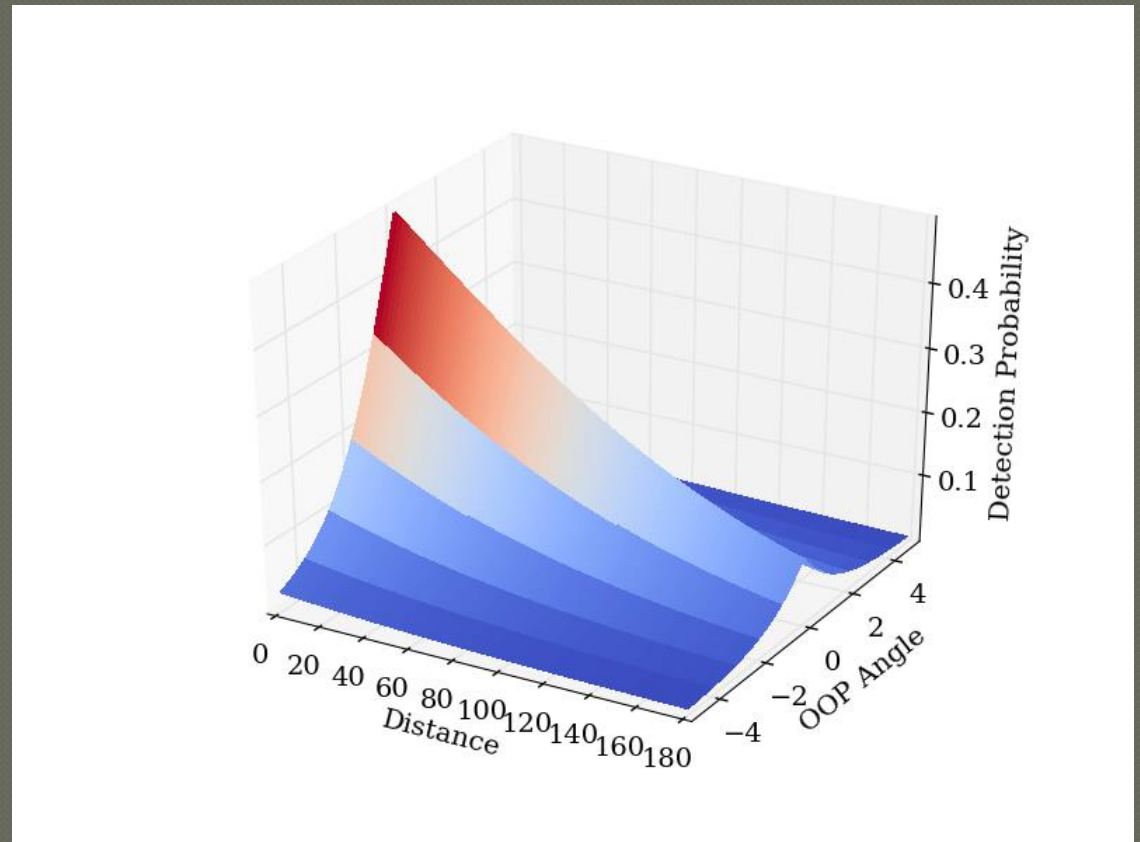

Model Parameters – Event

- Hydro Event Locations are uniform over the earth's water surface area at a rate of 1 per hour
- Event Energy has Cauchy(70, 10) distribution
(units: db re J/m²/Hz)

Station Detection Probability

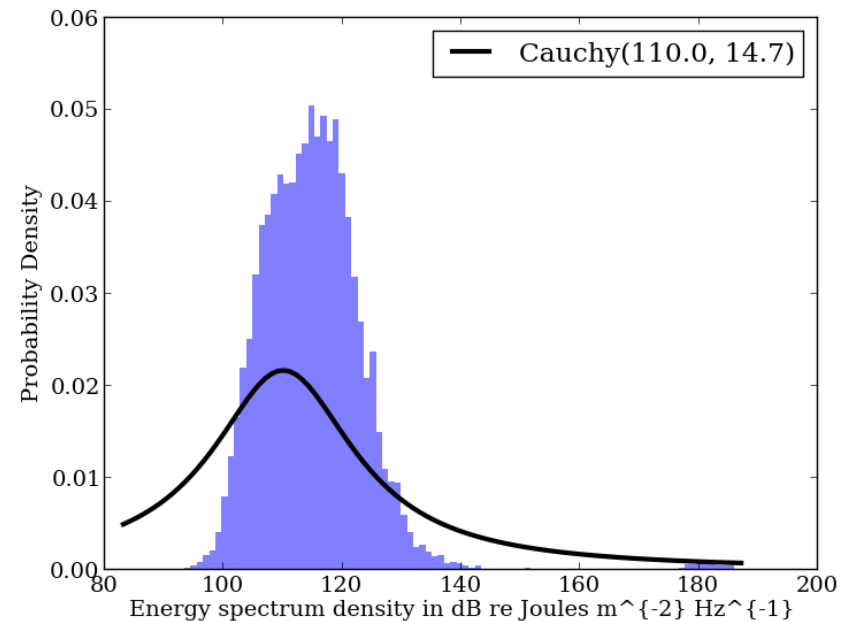

Energy

- Energy losses are mainly due to geometric spreading (cylindrical in the deep sound channel) with very little absorption

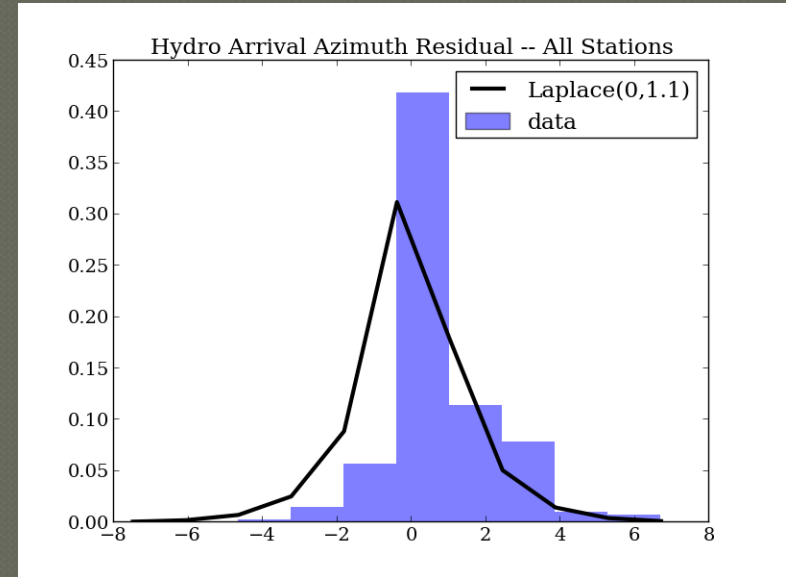

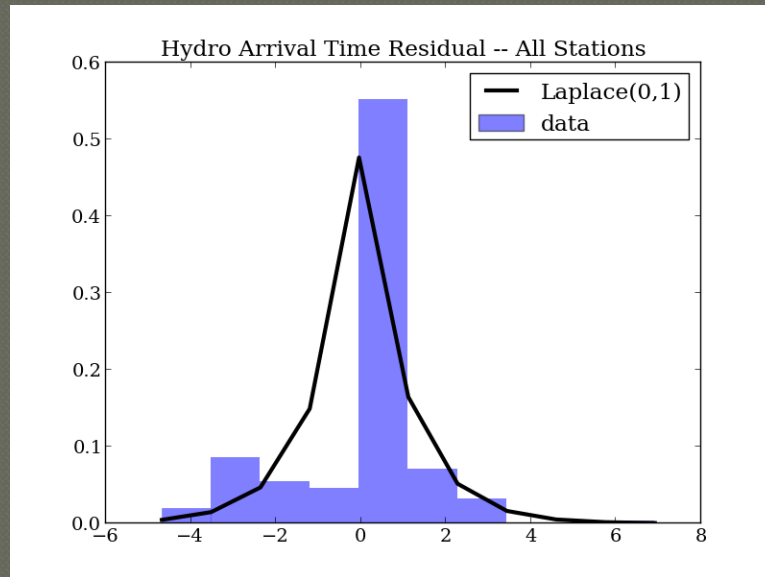

Hydro Arrival Energy vs Distance

Unassociated Hydro Arrival Energy at HydroPhone Stations

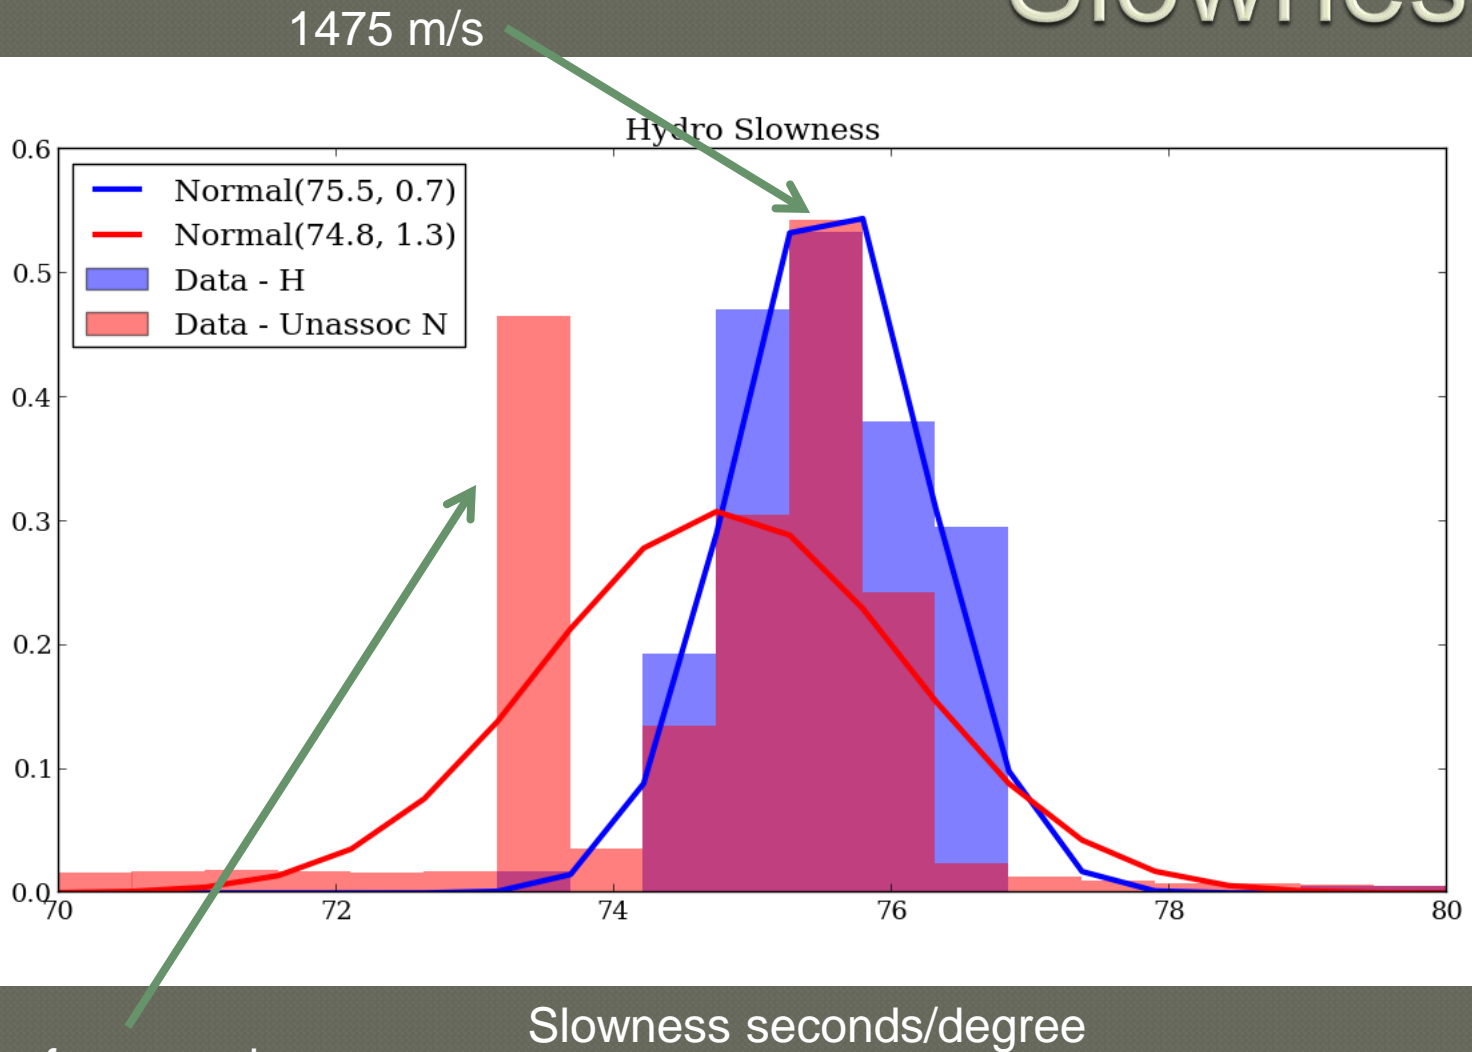

Azimuth, Time

- Arrival Time Residual \sim Laplace(0,1) sec
- Arrival Azimuth Residual \sim Laplace(0,1.1) deg
- Noise is uniform for both

Slowness

Faster noise from nearby sources

Inference

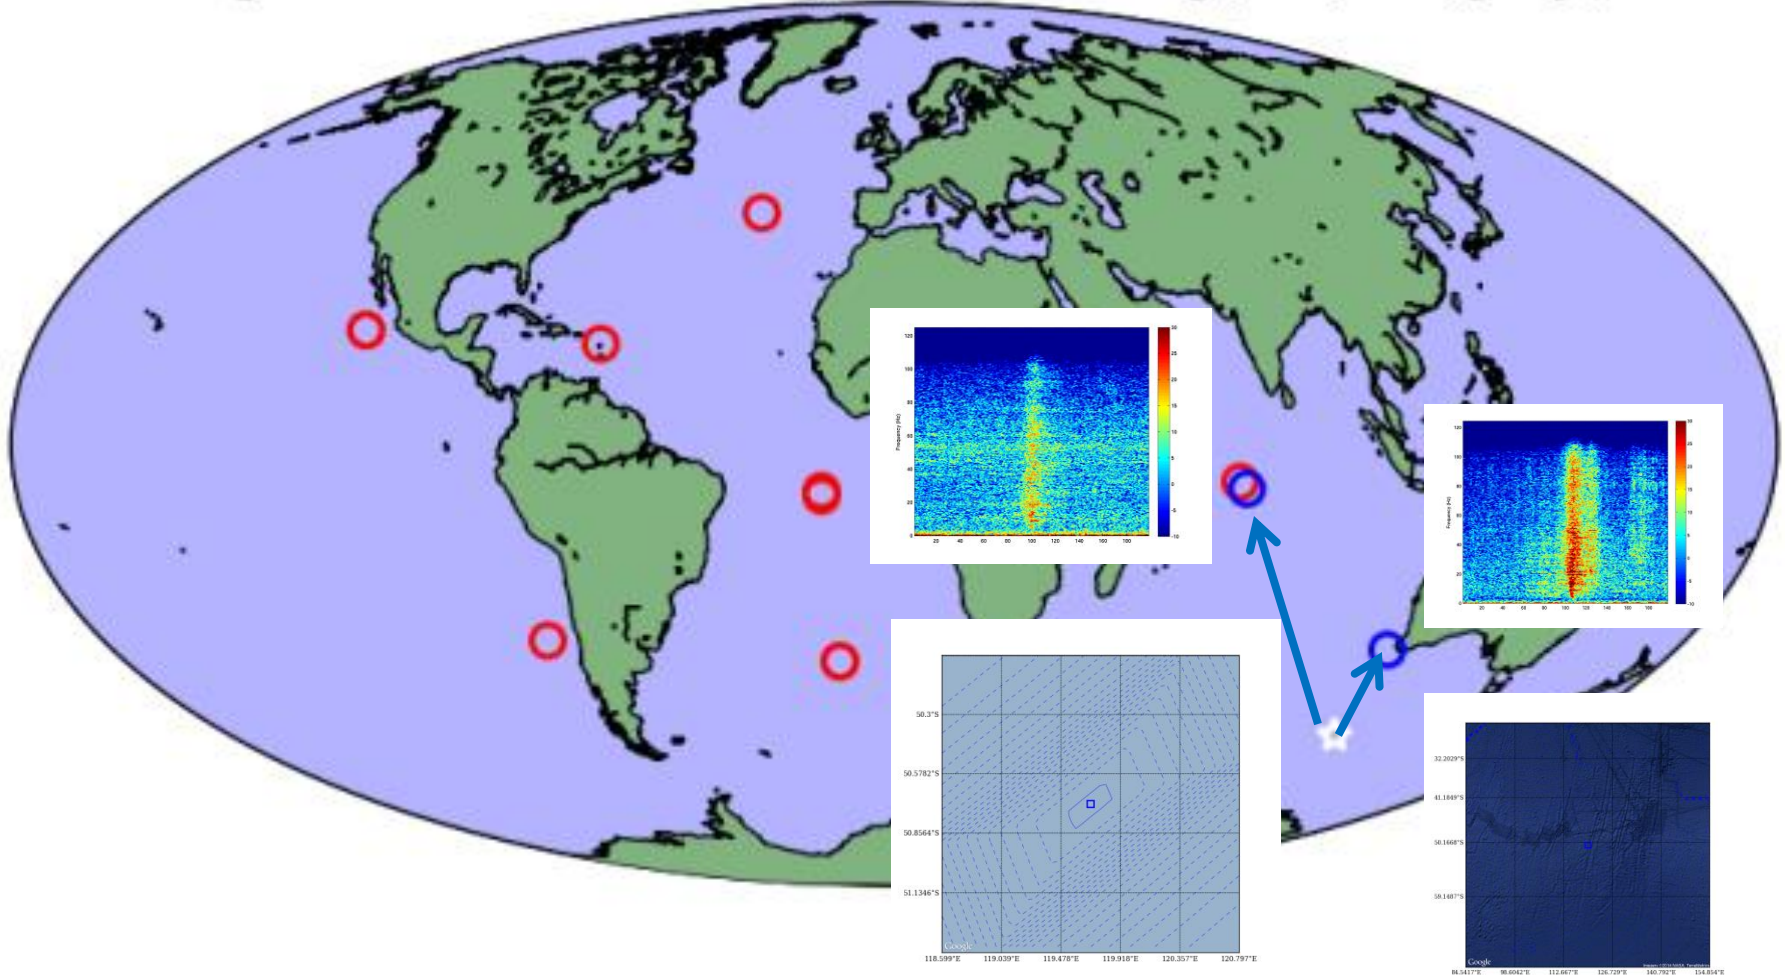

- We want all events such that:
 - Probability of event being generated plus associated arrivals generated from the event higher than noise generating the same arrivals
 - Simple sequence of birth, re-locate, re-associate, and death moves
 - The model dictates all choices

Results on 2010 Events

- ◉ NET-VISHA found 12/26 hydro LEB events
- ◉ SEL3 found 16/26 (but LEB is built from SEL3)
- ◉ 129 “very promising” events vs 54 such events in SEL3
- ◉ Seismic Accuracy goes from 89.8% -> 90.0% (small, but consistent)
- ◉ T phases 25% missed 20% additional

One of the Promising Events

P phase: sites detecting(blue) missing(red) off(grey)

Ahyl Seamount

Ahyl Seamount

- Currently active underwater volcano (20.43 N 145.04 E). Went active on April 23, 2014
- Experiment conducted on April 24 data
- In 2 degree ball around volcano
 - NET-VISHA found 18
 - SEL3 (GA) found 5
- In the 2 degree ball with 3 stations
 - NET-VISHA found 15
 - SEL3 (GA) found 0

Conclusions

- Seismic model extended to include hydro
- Model parameters heavily influenced by domain expertise, since there is very little data
- No significant changes in inference
- Results on 2010 show high quality events jumped up nearly 3 times high vs SEL3
- Blind test on Ahyl Seamount found 15 new REB-quality events in one day.
